Options

Option

An option gives its owner the right, but not the obligation, to call (buy) or put (sell) an underlying asset at a strike price on a fixed expiration date.

Options

Option

An option gives its owner the right, but not the obligation, to call (buy) or put (sell) an underlying asset at a strike price on a fixed expiration date.

- european options

Options

Option

- american options

Options

Option

An option gives its owner the right, but not the obligation, to call (buy) or put (sell) an underlying asset at a strike price on a fixed expiration date.

- european options
- american options
- exotic options

European options

Value of european option at its expiration time:

- Call: $C_T = \max\{S_T - K, 0\}$

European options

Value of european option at its expiration time:

- Call: $C_T = \max\{S_T - K, 0\}$
- Put: $P_T = \max\{K - S_T, 0\}$

Black-Scholes model

Price of european call option:

- $V_t = S_t \Phi(d_1) - Ke^{-R(T-t)} \Phi(d_2)$
 - K ... strike price
 - R ... risk-free interest rate
 - S_t ... the underlying asset's value at time t
- $d_1 = \frac{\ln(\frac{S_t}{K} e^{RT}) + \frac{\sigma^2}{2} T}{\sigma \sqrt{T}}$
- $d_2 = d_1 - \sigma \sqrt{T}$

VaR

VaR definiton

Let X be a random variable on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$ and $\alpha \in (0, 1)$. $\text{VaR}_\alpha(X)$ is defined as the $(1 - \alpha)$ quantile of $-X$. Then

$$\text{VaR}_\alpha(X) := -\inf\{x \in \mathbb{R} \mid F_X(x) > \alpha\} = F_{-X}^{-1}(1 - \alpha).$$

Non-linear VaR

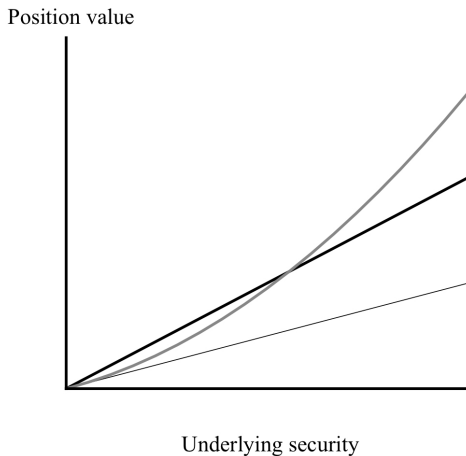

Figure: Linear and non-linear function of payoff.

The Delta

The Delta of an option tells us how much an option price would change relative to a change in the price of the underlying asset.

The Delta

The Delta of an option tells us how much an option price would change relative to a change in the price of the underlying asset.

$$\Delta = \frac{\partial V}{\partial S}$$

The Delta

The Delta of an option tells us how much an option price would change relative to a change in the price of the underlying asset.

$$\Delta = \frac{\partial V}{\partial S}$$

- Call: $\Delta \in [0, 1]$

The Delta

The Delta of an option tells us how much an option price would change relative to a change in the price of the underlying asset.

$$\Delta = \frac{\partial V}{\partial S}$$

- Call: $\Delta \in [0, 1]$
- Put: $\Delta \in [-1, 0]$

The Delta

The Delta of an option tells us how much an option price would change relative to a change in the price of the underlying asset.

$$\Delta = \frac{\partial V}{\partial S}$$

- Call: $\Delta \in [0, 1]$
- Put: $\Delta \in [-1, 0]$
- European call option: $\Phi(d_1)$

The Gamma

The Gamma measures the change in an option's delta relative to changes in the underlying asset price.

The Gamma

The Gamma measures the change in an option's delta relative to changes in the underlying asset price.

$$\Gamma = \frac{\partial^2 V}{\partial S^2}$$

The Gamma

The Gamma measures the change in an option's delta relative to changes in the underlying asset price.

$$\Gamma = \frac{\partial^2 V}{\partial S^2}$$

- European call option: $e^{-R(T-t)} \frac{\Phi(d1)}{S_t \sigma \sqrt{T-t}}$

The Gamma

The Gamma measures the change in an option's delta relative to changes in the underlying asset price.

$$\Gamma = \frac{\partial^2 V}{\partial S^2}$$

- European call option: $e^{-R(T-t)} \frac{\Phi(d1)}{S_t \sigma \sqrt{T-t}}$

In general, the gamma is at its maximum point when the stock is near the strike of the option.

The Theta

The Theta measures an options sensitivity to time and tells us how susceptible is an option's value to the passage of time.

The Theta

The Theta measures an options sensitivity to time and tells us how susceptible is an option's value to the passage of time.

$$\Theta = \frac{\partial V}{\partial t}$$

The Theta

The Theta measures an options sensitivity to time and tells us how susceptible is an option's value to the passage of time.

$$\Theta = \frac{\partial V}{\partial t}$$

- An option's potential drops as time moves on.

The Theta

The Theta measures an options sensitivity to time and tells us how susceptible is an option's value to the passage of time.

$$\Theta = \frac{\partial V}{\partial t}$$

- An option's potential drops as time moves on.

Long positions generally have a negative theta and short positions a positive one.

The Vega

The Vega measures an options sensitivity to volatility.

The Vega

The Vega measures an options sensitivity to volatility.

$$\mathcal{V} = \frac{\partial V}{\partial \sigma}$$

The Vega

The Vega measures an options sensitivity to volatility.

$$\mathcal{V} = \frac{\partial V}{\partial \sigma}$$

As an amount by which the option price changes when the volatility changes, vega is always a positive number.

Delta-Gamma-Theta Approach

Incorporation of greek parameters into the VaR can provide a more accurate estimate of the risk of loss on option portfolio.

Delta-Gamma-Theta Approach

Incorporation of greek parameters into the VaR can provide a more accurate estimate of the risk of loss on option portfolio.

Importance of the three Greeks used for VaR calculation:

Delta-Gamma-Theta Approach

Incorporation of greek parameters into the VaR can provide a more accurate estimate of the risk of loss on option portfolio.

Importance of the three Greeks used for VaR calculation:

- Delta: the potential change in the option's value associated with a unit shift in the underlying asset's price;

Delta-Gamma-Theta Approach

Incorporation of greek parameters into the VaR can provide a more accurate estimate of the risk of loss on option portfolio.

Importance of the three Greeks used for VaR calculation:

- Delta: the potential change in the option's value associated with a unit shift in the underlying asset's price;
- Gamma: important role in VaR calculations as the underlying asset price fluctuates more significantly;

Delta-Gamma-Theta Approach

Incorporation of greek parameters into the VaR can provide a more accurate estimate of the risk of loss on option portfolio.

Importance of the three Greeks used for VaR calculation:

- Delta: the potential change in the option's value associated with a unit shift in the underlying asset's price;
- Gamma: important role in VaR calculations as the underlying asset price fluctuates more significantly;
- Theta: time decay is a major factor in the approximation of the overall risk of the portfolio.
